

Introduction

- Studies that focus on species richness can't account important information to fully understand the spatial variation
- We investigated the effects of historical factors to the European dragonfly diversity
- Tested the patterns of how unique the species is to an area and how different the species are from each other
- Which pattern has more spatial variation?

Methods

- Combine distribution data
- Phylogenetic tree of 122 European dragonfly species
- Measures of diversity leading to calculating

Results & Discussion

- Spatial structure in patterns can be showed in the Fig.
- Areas south show higher phylogenetic diversity (more species, small distributions)
- Increase in proportion of lentic species being more widespread and closed related
- Across 4192 groups of European dragonflies, historical processes are major to understand the current spatial patterns
